8.7 Prufer sequence

In combinatorial mathematics, the Prufer sequence of a labeled tree is a unique sequence associated with the tree. The sequence for a tree on n vertices has length $n-2$.

One can generate a labeled tree's Prufer sequence by iteratively removing vertices from the tree until only two vertices remain. Specifically, consider a labeled tree T with vertices $1, 2, ..., n$. At step i, remove the leaf with the smallest label and set the ith element of the Prufer sequence to be the label of this leaf's neighbour.

One can generate a labeled tree from a sequence in three steps. The tree will have $n+2$ nodes, numbered from 1 to $n+2$. For each node set its degree to the number of times it appears in the sequence plus 1. Next, for each number in the sequence $a[i]$, find the first (lowest-numbered) node, j, with degree equal to 1, add the edge $(j, a[i])$ to the tree, and decrement the degrees of j and $a[i]$. At the end of this loop two nodes with degree 1 will remain (call them u, v). Lastly, add the edge (u, v) to the tree.

The Prufer sequence of a labeled tree on n vertices is a unique sequence of length $n-2$ on the labels 1 to n - this much is clear. Somewhat less obvious is the fact that for a given sequence S of length $n-2$ on the labels 1 to n, there is a unique labeled tree whose Prufer sequence is S.

8.8 Spanning tree counting

Kirchhoff's Theorem: the number of spanning trees in a graph G is equal to *any* cofactor of the Laplacian matrix of G, which is equal to the difference between the graph's degree matrix (a diagonal matrix with vertex degrees on the diagonals) and its adjacency matrix (a (0,1)-matrix with 1's at places corresponding to entries where the vertices are adjacent and 0's otherwise).

The number of edges with a certain weight in a minimum spanning tree is fixed given a graph. Moreover, the number of its arrangements can be obtained by finding a minimum spanning tree, compressing connected components of other edges in that tree into a point, and then applying Kirrchoff's theorem with only edges of the certain weight in the graph. Therefore, the number of minimum spanning trees in a graph can be solved by multiplying all numbers of arrangements of edges of different weights together.

8.9 Mobius inversion

8.9.1 Mobius inversion formula

$$[x = 1] = \sum_{d|x} \mu(d)$$

$$x = \sum_{d|x} \mu(d)$$

8.9.2 Gcd inversion

$$\begin{aligned}
\sum_{a=1}^{n}\sum_{b=1}^{n} gcd^2(a,b) &= \sum_{d=1}^{n} d^2 \sum_{i=1}^{\lfloor \frac{n}{d} \rfloor}\sum_{j=1}^{\lfloor \frac{n}{d} \rfloor} [gcd(i,j) = 1] \\
&= \sum_{d=1}^{n} d^2 \sum_{i=1}^{\lfloor \frac{n}{d} \rfloor}\sum_{j=1}^{\lfloor \frac{n}{d} \rfloor} \sum_{t|gcd(i,j)} \mu(t) \\
&= \sum_{d=1}^{n} d^2 \sum_{t=1}^{\lfloor \frac{n}{d} \rfloor} \mu(t) \sum_{i=1}^{\lfloor \frac{n}{d} \rfloor} [t|i] \sum_{j=1}^{\lfloor \frac{n}{d} \rfloor} [t|j] \\
&= \sum_{d=1}^{n} d^2 \sum_{t=1}^{\lfloor \frac{n}{d} \rfloor} \mu(t) \lfloor \frac{n}{dt} \rfloor^2
\end{aligned}$$

The formula can be computed in $O(nlogn)$ complexity.

Moreover, let $l = dt$, then

$$\sum_{d=1}^{n} d^2 \sum_{t=1}^{\lfloor \frac{n}{d} \rfloor} \mu(t) \lfloor \frac{n}{dt} \rfloor^2 = \sum_{l=1}^{n} \lfloor \frac{n}{l} \rfloor^2 \sum_{d|l} d^2 \mu(\frac{l}{d})$$

Let $f(l) = \sum_{d|l} d^2 \mu(\frac{l}{d})$. It can be proven that $f(l)$ is multiplicative. Besides, $f(p^k) = p^{2k} - p^{2k-2}$.

Therefore, with linear sieve the formula can be computed in $O(n)$ complexity.

8.10 2-SAT

In terms of the implication graph, two literals belong to the same strongly connected component whenever there exist chains of implications from one literal to the other and vice versa. Therefore, the two literals must have the same value in any satisfying assignment to the given 2-satisfiability instance. In particular, if a variable and its negation both belong to the same strongly connected component, the instance cannot be satisfied, because it is impossible to assign both of these literals the same value. As Aspvall et al. showed, this is a necessary and sufficient condition: a 2-CNF formula is satisfiable if and only if there is no variable that belongs to the same strongly connected component as its negation.

This immediately leads to a linear time algorithm for testing satisfiability of 2-CNF formulae: simply perform a strong connectivity analysis on the implication graph and check that each variable and its negation belong to different components. However, as Aspvall et al. also showed, it also leads to a linear time algorithm for finding a satisfying assignment, when one exists. Their algorithm performs the following steps:

Construct the implication graph of the instance, and find its strongly connected components using any of the known linear-time algorithms for strong connectivity analysis.

Check whether any strongly connected component contains both a variable and its negation. If so, report that the instance is not satisfiable and halt.

Construct the condensation of the implication graph, a smaller graph that has one vertex for each strongly connected component, and an edge from component i to component j whenever the implication graph contains an edge uv such that u belongs to component i and v belongs to component j. The condensation is automatically a directed acyclic graph and, like the implication graph from which it was formed, it is skew-symmetric.

Topologically order the vertices of the condensation. In practice this may be efficiently achieved as a side effect of the previous step, as components are generated by Kosaraju's algorithm in topological order and by Tarjan's algorithm in reverse topological order.

For each component in the reverse topological order, if its variables do not already have truth assignments, set all the literals in the component to be true. This also causes all of the literals in the complementary component to be set to false.

9.2 Regular expression

9.2.1 Special pattern characters

Characters	Description
`.`	Not newline
`\t`	Tab (HT)
`\n`	Newline (LF)
`\v`	Vertical tab (VT)
`\f`	Form feed (FF)
`\r`	Carriage return (CR)
`\cletter`	Control code
`\xhh`	ASCII character
`\uhhhh`	Unicode character
`\0`	Null
`\int`	Backreference
`\d`	Digit
`\D`	Not digit
`\s`	Whitespace
`\S`	Not whitespace
`\w`	Word (letters, numbers and the underscore)
`\W`	Not word
`\character`	Character
`[class]`	Character class
`[^class]`	Negated character class

9.2.2 Quantifiers

Characters	Times
`*`	0 or more
`+`	1 or more
`?`	0 or 1
`{int}`	`int`
`{int,}`	`int` or more
`{min,max}`	Between `min` and `max`

By default, all these quantifiers are greedy (i.e., they take as many characters that meet the condition as possible). This behavior can be overridden to ungreedy (i.e., take as few characters that meet the condition as possible) by adding a question mark (`?`) after the quantifier.

9.2.3 Groups

Characters	Description
`(subpattern)`	Group with backreference
`(?:subpattern)`	Group without backreference

9.2.4 Assertions

Characters	Description
`^`	Beginning of line
`$`	End of line
`\b`	Word boundary
`\B`	Not a word boundary
`(?=subpattern)`	Positive lookahead
`(?!subpattern)`	Negative lookahead

9.2.5 Alternative

A regular expression can contain multiple alternative patterns simply by separating them with the separator operator (`|`): The regular expression will match if any of the alternatives match, and as soon as one does.

9.2.6 Character classes

Class	Description
`[:alnum:]`	Alpha-numerical character
`[:alpha:]`	Alphabetic character
`[:blank:]`	Blank character
`[:cntrl:]`	Control character
`[:digit:]`	Decimal digit character
`[:graph:]`	Character with graphical representation
`[:lower:]`	Lowercase letter
`[:print:]`	Printable character
`[:punct:]`	Punctuation mark character
`[:space:]`	Whitespace character
`[:upper:]`	Uppercase letter
`[:xdigit:]`	Hexadecimal digit character
`[:d:]`	Decimal digit character
`[:w:]`	Word character
`[:s:]`	Whitespace character

Please note that the brackets in the class names are additional to those opening and closing the class definition. For example:

`[[:alpha:]]` is a character class that matches any alphabetic character.

`[abc[:digit:]]` is a character class that matches a, b, c, or a digit.

`[^[:space:]]` is a character class that matches any character except a whitespace.
